#### IV. Conclusions

The statistical analyses summarized herein have been examined, as yet, in only a preliminary fashion. Hence, relatively few interpretive \_ comments are contained in this report. The major need for explication of the separate effects of variable cover types, soil moisture profiles, soil textures and the sensor variables - especially the actual response kernels or response weighting functions - is rendered difficult by the convolution of all these variables. The statistical analyses contained within this report are intended as helps toward that end. Such interpretive efforts remain to be done. Finally, the continued review of the analyses efforts of other researchers in this field and the comparative examination of their and our results also remains to be done. For example, Lees (1982) shows a marked difference in his conclusions vis a vis those of Schmugge (1980) on the utility of soil texture for the normalization of the volumetric soil moisture data.
